Summary

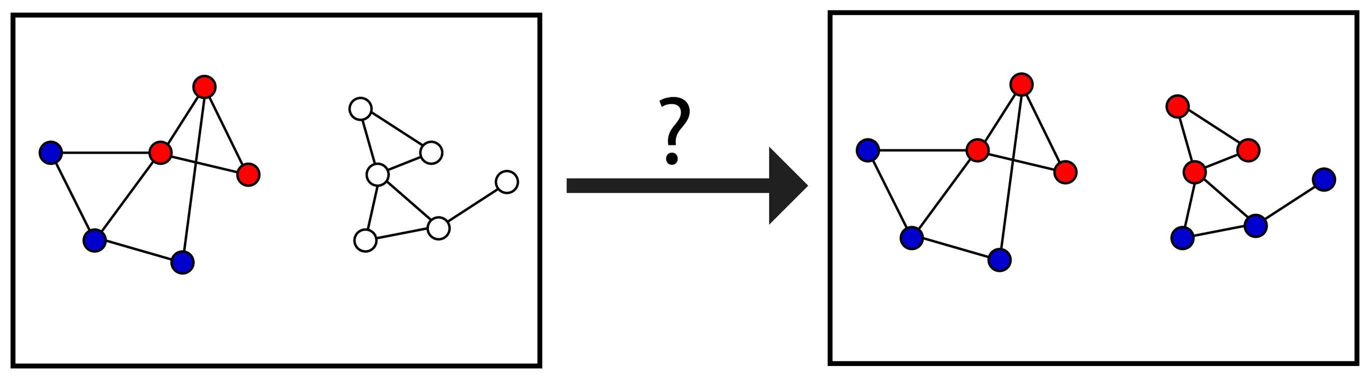
We tackle the problem of **node classification** where the goal is to classify nodes in a graph by leveraging nodes' features and graph structure. We focus on **semi-supervised** settings where only a subset of nodes is labelled and we aim at **transferring knowledge** across labelled and unlabelled nodes.

- **Problem:** node classification on a new population, not connected to the labelled nodes
- **Solution:** hallucinate edges between the labelled nodes and the unlabelled nodes, to reinforce the information flow
- **Results:** our method achieves +3.6% and +3.4% gain in accuracy over standard baselines on `cora` and `citeseer` datasets.

Problem Setup

Input:

- adjacency matrices A_L and A_U for the two sets of nodes;
- features vectors X_L and X_U;
- labels y_L

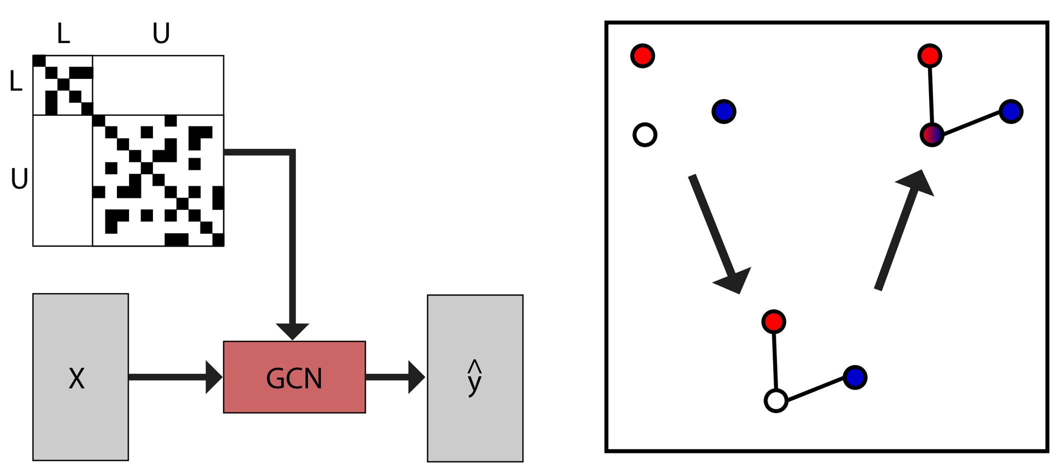


Output:

- predictions for the unlabelled nodes $\hat{y}_L$

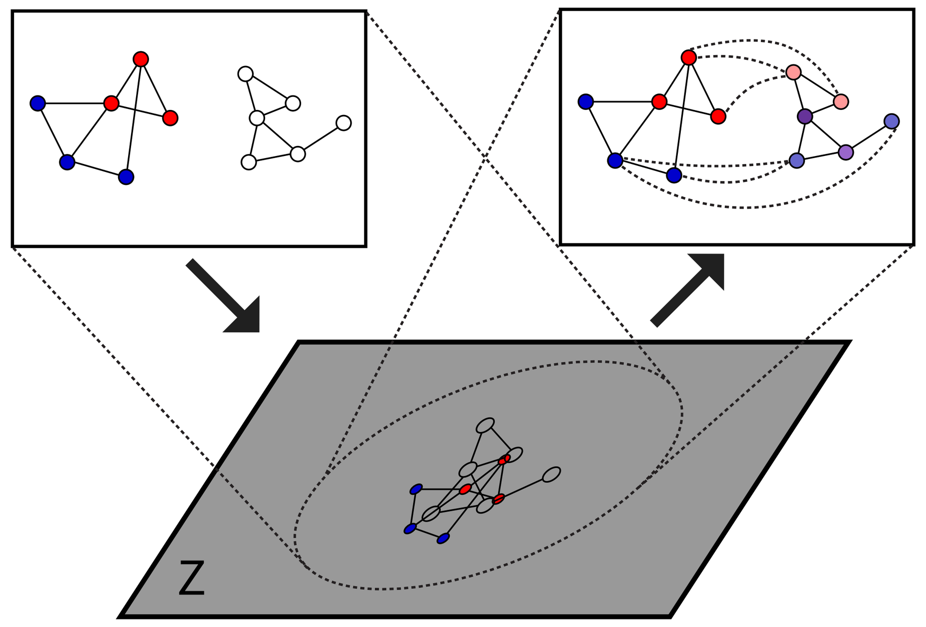
Baseline model

`GCN` [1] for node classification: $\hat{y} = h(Ah(AXW_1)W_2)$



Approach - Hallucigraph

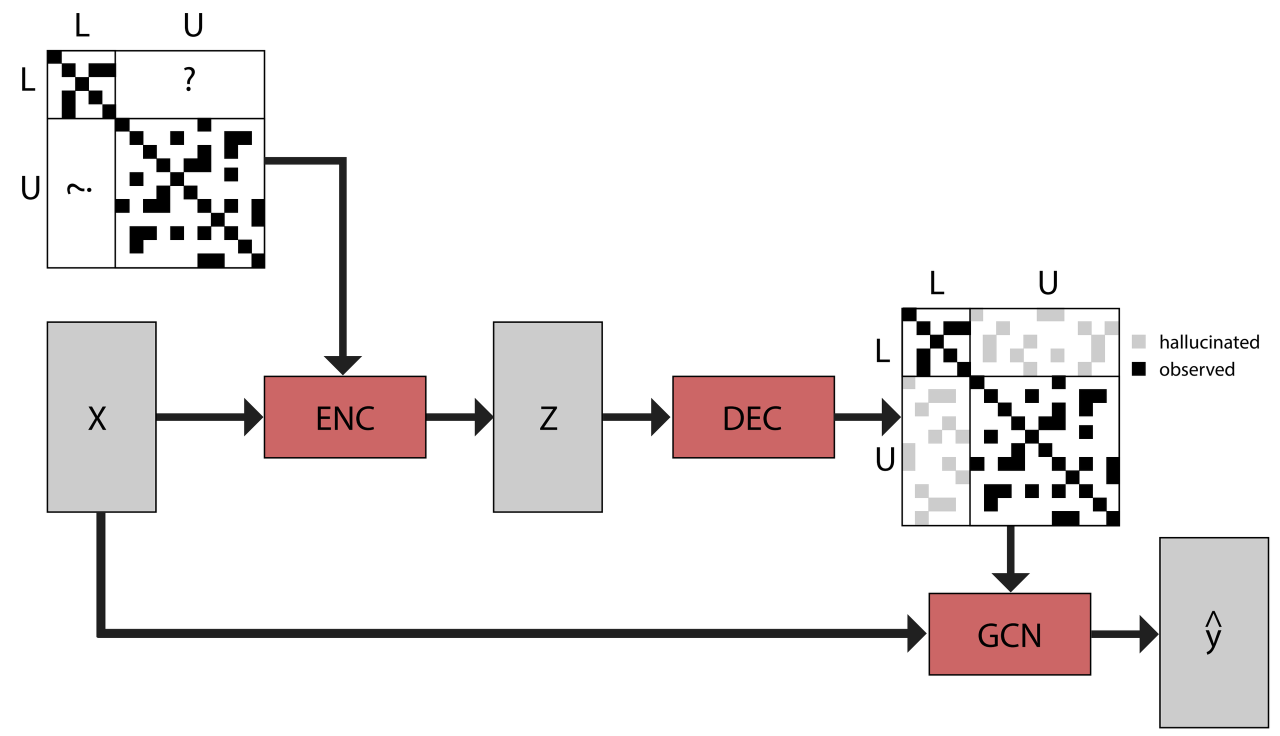
- learn low-dimensional node embeddings to encode node similarity (`VGAE` [2])
- hallucinate edges and complete the adjacency matrix (edges)
- run a `GCN` with the completed adjacency to predict node labels



$$Z \sim \mathcal{N}(\mu_Z, \sigma_Z^2) \quad \text{and} \quad \tilde{A} = \sigma(ZZ^T).$$

with $\mu_Z, \sigma_Z = \mathrm{GCN}(A, X)$

$$\mathcal{L}_{LP} = -\mathbb{E}_{Z\sim q(Z|A,X)}[A_{ij}\log\tilde{A}_{ij} + (1-A_{ij})\log(1-\tilde{A}_{i,j})] + \mathrm{KL}(q(Z|A,X)||p(Z)).$$

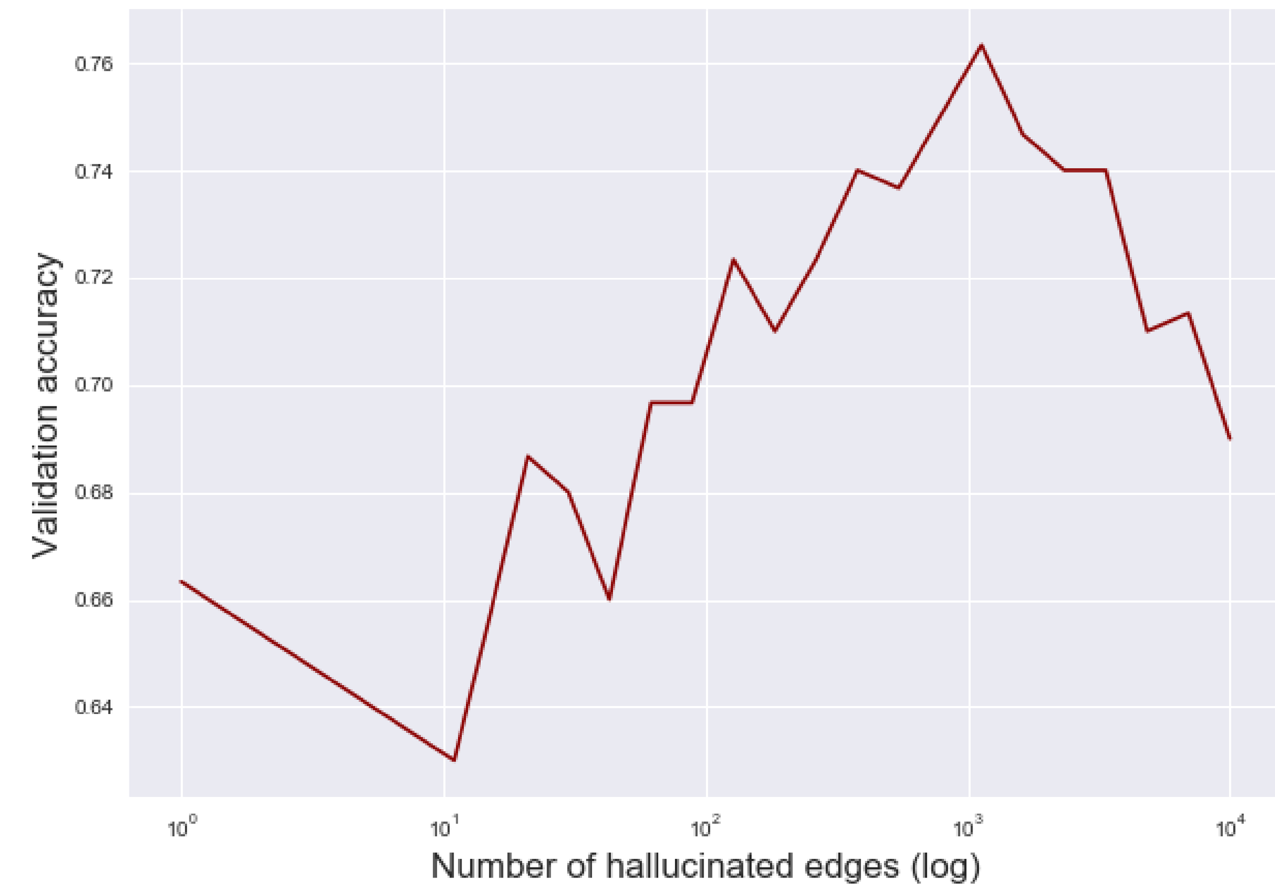


produces $\hat{A}$:

- top$K$ (K hyper-parameter)
- sampling using gumbel softmax [4] trick (allows gradients to flow)

$\hat{y} = \mathrm{GCN}(\hat{A}, X)$

Results



Model	cora	citeseer
MLP	56.4%	56.8 %
GCN	71.3%	65.8%
Hallucigraph	**74.9%**	**69.2%**

Accuracy results for node classification task on three publication datasets where we removed all LU edges; using plain nodes features without edges (MLP); using the edges within labelled nodes and within unlabelled nodes (GCN); using Hallucigraph.

- As shown in [1], the GCN improves on standalone MLP by leveraging the connections between nodes
- By adding "hallucinated" edges, we improve the connectivity structure, and we obtain more predictive power
